For data related questions, please contact peiley@berkeley.edu.

This document last updated: April 22, 2020. Data last updated: April 6, 2020.

The Supplementary Information contains three sections: Supplementary Notes, Supplementary Methods, and Supplementary Tables.

The Supplementary Notes section describes the data acquisition and processing procedure for the epidemiological and policy data used in this paper. The sources for both types of data come from a variety of in-country data sources, which include government public health websites, regional newspaper articles, and Wikipedia crowd-sourced information. We have supplemented this data with international data compilations. A list of the epidemiological and policy data compiled for this analysis can be found [here](#).

The Supplementary Methods section describes sensitivity analyses and simulations performed to verify the robustness of our model, including: the sensitivity of our regression model and counterfactual projections to varying epidemiological parameters; and the sensitivity of our estimates to alternative lag structures, withholding of data, and differing policy groupings.

The Supplementary Tables section contains tables detailing: 1) the number of anti-contagion policies tabulated by administrative division in each country; 2) epidemiological data in Wuhan prior to policy intervention, and estimates of the initial infection growth rate and case doubling times; and 3) the main regression results estimating the effect of policy on growth rates.

Supplementary Notes

Epidemiological Data

The epidemiological datasets and sources used in this paper are described below. The main health variables of interest are:

1. “*cum_confirmed_cases*”: The total number of confirmed positive cases in the administrative area since the first confirmed case.
2. “*cum_deaths*”: The total number of individuals that have died from COVID-19.
3. “*cum_recoveries*”: The total number of individuals that have recovered from COVID-19.
4. “*cum_hospitalized*”: The total number of hospitalized individuals.
5. “*cum_hospitalized_symptom*”: The total number of symptomatic hospitalized individuals.
6. “*cum_intensive_care*”: The total number of individuals that have received intensive care.
7. “*cum_home_confinement*”: The total number of individuals that have been self-quarantined in their homes as a result of a positive test.
8. “*active_cases*”: The number of individuals who currently still test positive on the date of the observation.
9. “*active_cases_new*”: The number of new active cases since the previous date.
10. “*cum_tests*”: The total number of tests (includes both positive and negative results) conducted in an administrative unit.

Additional metadata accompanying the health outcome variables:

1. “*date*”: The date of observation.
2. “*adm0_name*”: The ISO3 (country) code to which this observation belongs.
3. “*adm1_name*”: The name of the “Adm1” region (typically state or province) to which this observation belongs.
4. “*adm2_name*”: If the dataset contains observations at the “Adm2” level, then this is the name of the “Adm2” region to which this observation belongs (e.g. counties in the United States).
5. “*adm[1,2]_id*”: Any alphanumeric ID scheme to identify different administrative units (e.g. FIPS code in the United States).
6. “*lat*”: The latitude of the centroid of the administrative unit.
7. “*lon*”: The longitude of the centroid of the administrative unit.
8. “*policies_enacted*”: The number of active policies that are in place for the administrative unit as of that date. This variable is not population weighted.
9. “*testing_regime*”: A categorical variable used to identify when an administrative region changed their COVID-19 testing regime. This is zero-indexed, with the ordering only indicating chronological progression (there is no external meaning to Regime 2 vs. Regime 1 vs. Regime 0, and there is no consistency enforced for coding across countries). For example, if China changes their testing regime twice, all observations prior to the first regime change would be coded “*testing_regime*=0,” all observations in between the two changes would be coded

“testing_regime=1,” and all observations after the second change would be coded “testing_regime=2.”

10. “population”: The population of the administrative unit.
11. “pop_is_imputed”: A binary variable equal to 1 if the population is imputed, and 0 otherwise. Used for imputing the population of some cities in China.

Data Imputation:

In instances where health outcome observations are missing or suffer from data quality issues, we have imputed to fill in the missing values. Imputed health outcome variables are denoted by “[health_outcome]_imputed.” For the majority of our analyses we do not use imputed data; France is the exception where we impute two days of missing data. We do this to ensure we have variation in policy variables for use in the analysis.

We impute by:

1. Taking the natural log of the non-missing observations pertaining to that health outcome variable.
2. Linearly interpolating over the missing dates for that health outcome variable.
3. Exponentiating the interpolated values back into levels and rounding to the nearest integer.

China

We have collated a city-level time series health outcome dataset in China for 339 cities from January 10, 2020 to April 7, 2020.

For data from January 24, 2020 onwards, we relied on the public dataset Ding Xiang Yuan¹ (DXY) that reports daily statistics across Chinese cities. Since DXY only publishes the most recent (cross-sectional) statistics (and not the historical data), we used the time series dataset scraped from DXY in an open source GitHub project². The web scraper program checks for updates at least once a day for the statistics published on DXY and records any changes in the number of cumulative confirmed cases, cumulative recoveries or cumulative deaths.

We assumed that no updates to the statistics meant there had been no new cases. We dropped a small number of cases that had been recorded but not assigned to a specific city (many of these cases are imported ones from other cities). We also dropped confirmed cases in prison populations (we assumed the spread of COVID-19 in prisons was not affected by the implementation of city-level lockdowns or travel ban policies).

For city level health outcomes prior to January 24, 2020, we manually collected official daily statistics from the central³ and provincial (Hubei,⁴ Guangdong,⁵ and Zhejiang⁶) Chinese government websites.

¹ [全球新冠病毒最新实时疫情地图 \(The latest real-time global COVID-19 map\)](#)

² [BlankerL/DXY-COVID-19-Data: 2019新型冠状病毒疫情时间序列数据仓库 \(COVID-19/2019-nCoV Infection Time Series Data Warehouse\)](#)

³ [疫情通报 \(National Health Commission of PRC; COVID-19 Report\)](#)

We did not collect city level health outcomes recorded prior to January 24, 2020 in provinces that had fewer than ten confirmed cases at that date. We made this decision since our analysis dropped observations with fewer than ten cumulative confirmed cases to prevent noisy data during the early transmission phase from disproportionately biasing the estimated results.

After merging the two datasets, we conducted a few quality checks:

(1) We checked that cumulative confirmed cases, cumulative recoveries, and cumulative deaths were increasing over time. In instances when cumulative outcomes decreased over time, we assumed that the recent numbers were more reliable, and treated the earlier number of cumulative cases as missing (this was often due to data entry errors or cases where patients that were reported to have been diagnosed with COVID-19, but were later found out to actually have tested negative). The magnitude of these errors was relatively small. We filled in any missing data with the imputation methodology described in the health data overview section.

(2) We validated our city-level dataset by aggregating observations up to the provincial level and comparing the time trends from the aggregated dataset to that of the provincial dataset collated by Johns Hopkins University.⁷ We confirmed that the two datasets matched very closely (see Figure A2 Panel A).

Testing Regime Changes:

During our sample period starting January 16, 2020, the criteria for being diagnosed with COVID-19 changed five times in China.⁸ On January 18, 2020, China began using the reverse transcription polymerase chain reaction (RT-PCR) test in addition to genome sequencing to confirm the SARS-CoV-2 infection in suspected cases.⁹ China also no longer required failure in antibiotic treatment and began considering patients who were not exposed to markets in Wuhan but had contact with symptomatic persons from Wuhan.¹⁰ On January 28, 2020, China began considering patients not necessarily linked to Wuhan with at least two out of the previous three required clinical manifestations.¹¹ On February 13, 2020, China created a separate “clinically confirmed” case definition for the Hubei province, which counted patients who met clinical criteria through chest imaging and may not have had epidemiological links or a positive PCR test.¹² On February 20, 2020, China reversed this decision and removed the separate “clinically confirmed” case definition for Hubei.¹³ On March 4, 2020, China

expanded the possible laboratory confirmation tests for SARS-CoV-2 to include serology.¹⁴ We included this information in the dataset because it could have potentially changed the levels and short-term growth rates of the number of confirmed cases.

The testing regime date changes are encoded within the data cleaning script.

France

We have collated a regional-level time series confirmed cases dataset in France from February 15, 2020 to March 25, 2020, and regional-level time series hospitalization data from March 3, 2020 to April 6, 2020.

We used the number of confirmed COVID-19 cases by *région* from France's government website.¹⁵ The sources listed for this dataset were the French public health website,¹⁶ the Ministry of Solidarity and Health,¹⁷ French newspapers that reported government information,¹⁸ and regional public health websites.¹⁹ Given that these data were not published on a daily basis, we supplemented the dataset by scraping the number of confirmed cases by *région* on the French public health website through March 25, 2020, which is the last date the subnational case data are made publicly available.²⁰

Hospitalization data come from the same source²¹ (*Santé Publique France*) as the case data. *Santé Publique France* announced they would stop posting regional-level case data because they were not reliable, and only provide hospitalization data instead.

Testing Regime Changes:

The one testing regime change in France occurred on March 13, 2020 with the beginning of the epidemic “stade 3”, when the government started to give severe cases in hospitals priority for testing.²² The testing regime date changes are encoded within the data cleaning script.

South Korea

We have collated a provincial-level time series health outcome dataset in South Korea from January 20, 2020 to April 6, 2020.

Most provinces in South Korea have been publishing data on their number of confirmed coronavirus cases. Seoul,²³ Daegu,²⁴ Gyeongsangbuk-do,²⁵ Jeollabuk-do,²⁶ and Sejong²⁷ provinces have been

²⁴ [대구광역시 코로나19 확진자 추이 \(Daegu COVID-19 The Confirmed Cases\)](#)

reporting the number of confirmed cases on a daily basis. For these provinces, we recorded this published health data.

Given that the province of Gangwon-do²⁸ does not report provincial-level health data, we refer to the daily number of new cases reported by each of its counties (Chuncheon-si,²⁹ Wonju-si,³⁰ Gangneung-si,³¹ Taebaek-si,³² Sokcho-si,³³ and Samcheok-si³⁴). As a result, we manually collected the number of new confirmed cases from each county's webpage and aggregated the numbers to the provincial level.

The remaining provinces (Gyeonggi-do,³⁵ Incheon,³⁶ Busan,³⁷ Ulsan,³⁸ Gwangju,³⁹ Chungcheongnam-do,⁴⁰ Chungcheongbuk-do,⁴¹ Gyeongsangnam-do,⁴² Jeju,⁴³ and Jeollanam-do⁴⁴) did not explicitly publish the number of cumulative confirmed cases. However, they did publish patient-level data, including the date when patients had tested positive. For these provinces, we constructed the measure of cumulative confirmed cases by counting the number of daily confirmed cases and adding it to the previous date's total.

Most provinces did not publish the number of deaths. Instead, we checked the daily policy briefings posted on the government homepages mentioned in the footnotes and manually collected mortality data. In instances when mortality data were not found in the briefings, we obtained the mortality data from other sources, such as through social media sources (e.g. Facebook) and blogs maintained by local governments. Lastly, we supplemented these sources with mortality data reported in news articles.

Testing regime changes:

We collected information on testing regime changes using press releases from the Korean Center for Disease Control and Prevention (KCDC). In the press release menu, the KCDC uploaded daily briefing announcements which contained information on testing criteria and changes to its testing regime.⁴⁵ Initially, the South Korean government only tested people who: 1) demonstrated respiratory

⁴⁵ [List | Press Release | News Room : KCDC](#)

symptoms within 14 days after visiting Wuhan South China Seafood Wholesale Market and 2) those who had pneumonia symptoms within 14 days after returning from Wuhan.⁴⁶

As the outbreak spread, the KCDC broadened the criteria for testing. Starting January 28, 2020, the agency isolated 1) those who had fever or respiratory symptoms upon returning from Hubei province and 2) those who had symptoms of pneumonia upon returning from mainland China.^{47,48} We coded this as the first change in the testing regime.

The second testing regime change occurred on February 4, 2020, when the KCDC announced that people who had had any “routine contacts” with confirmed cases were required to self quarantine for a 14-day period. The agency defines two categories of contacts: close contacts and routine contacts. The former is defined as a person who has been within two meters of, in the same room as, or exposed to any respiratory secretions of an infected individual. The latter refers to whether the individual conducted any activity in the same place and at the same time as the infected person. Prior to this regime change, the KCDC separated those two cases and applied different quarantine policies; starting February 4, 2020, any routine contacts were also required to be self-quarantined.⁴⁹

Shortly thereafter, South Korea aggressively expanded the scope of their testing. Starting February 7, 2020, the KCDC broadened the definition of suspected cases to 1) anyone who developed a fever or respiratory symptoms within 14 days after returning from China, 2) anyone who developed a fever or respiratory symptoms within 14 days after being in close contact with a confirmed case, and 3) anyone suspected of contracting COVID-19 based on their travel history to affected countries and their clinical symptoms.⁵⁰ Moreover, the KCDC announced that the test would be free for all suspected cases and confirmed cases.⁵¹ As a result of these efforts, KCDC announced that they would begin to test 3,000 people daily, a marked increase from only 200 people a day previously.⁵²

The KCDC revised their guidelines on February 20, 2020 in order to test more people. Their press release stated: “Suspected cases with a medical professional’s recommendation, regardless of travel history, will get tested. Additionally, those who are hospitalized with unknown pneumonia will also be tested. Lastly, anybody in contact with a diagnosed individual will need to self-isolate, and will only be released when they test negative on the thirteenth day of isolation.”⁵³

⁴⁸ NB: The KCDC English website explains the testing regime change in a more condensed format: “Any citizens identified with a fever or respiratory symptoms and have visited Wuhan will be isolated and tested at a nationally designated isolation hospital, and any foreigners staying in Korea will be conducted in cooperation with police.” [Urges cooperation in preventing the spread of 2019-nCoV in community | Press Release | News Room : KCDC](#)

⁴⁹ [알림> 보도자료 내용보기 " 신종 코로나바이러스 감염증 대응지침 일부 변경 " \(Revision in the Guidance Documents for COVID-19\)](#)

⁵⁰ [The updates on novel Coronavirus in Korea \(since 3 January\) | Press Release | News Room : KCDC](#)

NB: The date of this press release is February 8, 2020, but the definition of “suspected cases” was effective starting from February 7, 2020.

⁵¹ NB: The testing fee was already somewhat affordable; a person needed to pay 160,000 KRW (about \$130 USD). A related article can be found here: [5 신종코로나 진단검사 비용은 얼마? \(How much is the COVID-19 testing fee?\)](#)

⁵² [신종 코로나바이러스감염증 중앙사고수습본부 정례브리핑 \(2월 7일\) \(Daily briefing on COVID-19, February 7\)](#)

⁵³ [The updates of COVID-19\(as of Feb.19\) in Korea | Press Release | News Room : KCDC](#)

As the number of patients grew rapidly, the KCDC decided to focus on more vulnerable groups. In their February 29, 2020 press release, the agency stated: “The KCDC has asked local government and health facilities to focus on tests and treatment, especially targeting those aged 65+ and those with underlying conditions who need early detection and treatment.” This change was coded as our next testing regime change in the dataset.⁵⁴

On March 22, 2020, the KCDC began conducting COVID-19 diagnostic testing for every inbound traveler entering from Europe. This was coded as another testing regime change. Of the 1,442 inbound travelers from Europe arriving March 22, 2020, 152 were symptomatic and were quarantined and tested at an airport quarantine facility. The remaining 1,290 travelers were asymptomatic and were moved to a temporary living facility to be tested.⁵⁵

On March 27, 2020, this policy was expanded, where all inbound travellers from the US with symptoms (regardless of nationality) were required to be tested at the airport.⁵⁶ We code this as our final testing regime change.

The data on the testing regime date changes are in the “*KOR_policy_data_sources.csv*.”

Italy

We have collated a regional and provincial level time series health outcome dataset in Italy from February 24, 2020 to April 7, 2020.

This data came from the [GitHub repository](#) maintained by the Italian Department of Civil Protection (*Dipartimento della Protezione Civile*). Health outcomes included the number of confirmed cases, the number of deaths, the number of recoveries, and the number of active cases. These figures have been updating daily at 5 or 6 pm (Central European Time). The regional-level dataset was pulled directly from “*dati-regioni/dpc-covid19-ita-regioni.csv*,” and the provincial-level dataset was pulled from “*dati-province/dpc-covid19-ita-province.csv*.”

Testing regime changes:

The testing regime change in Italy occurred when the Director of Higher Health Council announced on February 26, 2020 that COVID-19 testing would only be performed on symptomatic patients, as the majority of the previous tests performed were negative.

The data on the testing regime date changes are in the “*ITA_policy_data_sources.csv*.”

Iran

We have collated a provincial-level time series health outcome dataset in Iran from February 19, 2020 to March 22, 2020.

⁵⁴ [The updates of COVID-19 in Korea \(As of 29 Feb. 2020\)](#)

⁵⁵ [List | Press Release | News Room : KCDC](#)

⁵⁶ [The updates on COVID-19 in Korea as of 27 March | Press Release | News Room : KCDC](#)

The Iranian government had been announcing its new daily number of COVID-19 confirmed cases at the provincial level on the Ministry of Health's website. This data has been compiled daily in the table "New COVID-19 cases in Iran by province"⁵⁷ located in the "2020 coronavirus pandemic in Iran" article on Wikipedia.

We spot-checked the data in the Wikipedia table against the Iranian Ministry of Health announcements⁵⁸ using a combination of Google Translate and a comparison⁵⁹ of the numbers in the announcements (which were written in Persian script) to the Persian numbers.

Testing regime changes:

On March 6, 2020, the Ministry of Health announced⁶⁰ a national coronavirus plan, which included contacting families by phone to identify potential cases, along with the disinfecting of public places. The plan was to begin in the provinces of Qom, Gilan, and Isfahan, and then would be rolled out nationwide. On March 13, 2020, the government announced a military-enforced home isolation policy throughout the nation.⁶¹ This announcement included nationwide disinfecting of public places. While a follow-up announcement of the March 6 high testing regime stating its complete rollout was not found, the March 13 announcement did reference the implementation of the public spaces component of the earlier plan across the country. We thus assumed that the high testing regime had also been fully rolled out on March 13, 2020.

The data on the testing regime date changes are in the "*IRN_policy_data_sources.csv*."

United States

We have collated a state-level time series health outcome dataset in the United States from January 22, 2020 to April 7, 2020.

The data come from the Github repository associated with the usafacts.org interactive dashboard. As of the time of writing, the data are available [here](#). The repository and dashboard are updated essentially in real-time, at least daily.

Testing regime changes:

To determine the testing regime, we used estimated daily counts of the cumulative number of tests conducted in every state, as aggregated by the largely crowdsourced effort named "The Covid Tracking Project" (covidtracking.com). We estimated the total number of tests as the sum of confirmed positive and negative cases. For some states and some days, there have been no negative case counts, in which case we utilize just the confirmed positive cases. We also ensured that the

⁵⁷ [2020 coronavirus pandemic in Iran](#)

⁵⁸ Example of Ministry of Health data:

[شناسایی 1209 بیمار جدید مبتلا به کووید 19 در کشور](#) (Identification of 1209 new patients with COVID-19 in the country)

⁵⁹ Google Translate sometimes translates various Persian numbers as "1". Persian numbers compared here: [Persian numbers](#)

⁶⁰ [ANOTHER senior Iranian official dies from coronavirus](#)

⁶¹ [Revolutionary Guards to enforce coronavirus controls in Iran](#)

confirmed number of positive cases agreed with the counts in the John Hopkins University COVID-19 dataset.⁶²

We programmatically determined possible testing regime changes by filtering for any consecutive days during which the testing rate increased at least 250% from one day to the next, and where this jump was an increase of at least 150 total tests over one day. After visually inspecting the candidates, we confirmed that the automatically detecting testing regime changes represent visually distinguishable changes in testing rates. The testing regime date changes are encoded within the data cleaning script.

Policy Data

The policy events, datasets, and sources used in this paper are described below. For each country, the relevant country-specific policies identified were then mapped to a harmonized policy categorization used across all countries.

The policy categories are by default coded as binary variables, where “[*policy_variable*]” = 0 before the policy is implemented in that area, and “[*policy_variable*]” = 1 on the date the policy is implemented (and for all subsequent dates until the policy is lifted). There are instances when the value of the policy variable is between 0 and 1; for further details, refer to the Policy Intensity subsection.

The main policy categories identified across the six different countries fall into four broad classes:

1. Restricting travel:
 - a. “*travel_ban_local*”: A policy that restricts people from entering or exiting the administrative area (e.g county or province) treated by the policy.
 - b. “*travel_ban_intl_in*”: A policy that either bans foreigners from specific countries from entering the country, or requires travelers coming from abroad to self-isolate upon entering the country.
 - c. “*travel_ban_intl_out*”: A policy that suspends international travel to specific foreign countries that have high levels of COVID-19 outbreak.
 - d. “*travel_ban_country_list*”: A list of countries for which the national government has issued a travel ban or advisory. This information supplements the policy variable “*travel_ban_intl_out*.”
 - e. “*transit_suspension*”: A policy that suspends any non-essential land-, rail-, or water-based passenger or freight transit.
2. Distancing through cancellation of events and suspension of educational/commercial/religious activities:
 - a. “*school_closure*”: A policy that closes school and other educational services in that area.

⁶² [CSSEGISandData/COVID-19: Novel Coronavirus \(COVID-19\) Cases, provided by JHU CSSE](https://covid19.jhu.edu/data/)

- b. *“business_closure”*: A policy that closes offices, non-essential businesses, and non-essential commercial activities in that area. “Non-essential” services are defined by area. This policy also includes the limiting of business hours and reducing restaurant and bar operations.
 - c. *“religious_closure”*: A policy that prohibits gatherings at a place of worship, specifically targeting locations that are epicenters of the COVID-19 outbreak. See the section on Korean policy for more information on this policy variable.
 - d. *“work_from_home”*: A policy that requires people to work remotely. This policy may also include encouraging workers to take holiday/paid time off.
 - e. *“event_cancel”*: A policy that cancels a specific pre-scheduled large event (e.g. parade, sporting event, etc). This is different from prohibiting all events over a certain size.
 - f. *“no_gathering”*: A policy that prohibits any type of public or private gathering. (whether cultural, sporting, recreational, or religious). Depending on the country, the policy can prohibit a gathering above a certain size, in which case the number of people is specified by the *“no_gathering_size”* variable.
 - g. *“no_gathering_inside”*: A policy that specifically prohibits indoor gatherings. See the section on French policy for more information on this policy variable.
 - h. *“no_demonstration”*: A policy that prohibits protest-specific gatherings. See the section on Korean policy for more information on this policy variable.
 - i. *“social_distance”*: A policy that encourages people to maintain a safety distance (often between one to two meters) from others. This policy differs by country, but includes other policies that close cultural institutions (e.g. museums or libraries), or encourage establishments to reduce density.
 - j. *“welfare_services_closure”*: A policy that mandates the closure of social welfare facilities, specifically mental rehabilitation facilities, social welfare centers, and homeless use facilities. See the section on Korean policy for more information on this policy variable.
3. Quarantine and lockdown:
- a. *“pos_cases_quarantine”*: A policy that mandates that people who have tested positive for COVID-19, or subject to quarantine measures, have to confine themselves at home. The policy can also include encouraging people who have fevers or respiratory symptoms to stay at home, regardless of whether they tested positive or not.
 - b. *“home_isolation”*: A policy that prohibits people from leaving their home regardless of their testing status. For some countries, the policy can also include the case when people have to stay at home, but are allowed to leave for work- or health-related purposes.
4. Additional policies
- a. *“emergency_declaration”*: A decision made at the city/municipality, county, state/provincial, or federal level to declare a state of emergency. This allows the affected area to marshal emergency funds and resources as well as activate emergency legislation.

- b. “*paid_sick_leave*”: A policy where employees receive pay while they are not working due to the illness.

Optional policies:

In the cases when the aforementioned policies are optional, we denote this as “[*policy_variable*]_{opt}.”

Population weighting of policy variables:

In cases where only a portion of the administrative unit (e.g. half of the counties within the state) are affected by the implementation of the policy, we weight the policy variable by the percentage of population within the administrative unit that is treated by the policy. This is denoted as “[*policy_variable*]_{popwt},” and the value that this variable can take on is a continuous number between 0 and 1. Sources for the population data are detailed in a later section.

Policy intensity:

“*policy_intensity*” is a continuous value between 0 and 1 that modulates the intensity/restrictiveness of a policy. By default this value is 0 when the policy has not been implemented and 1 when the policy is implemented (i.e. the policy variables are treated as indicator variables). However, in instances when a policy has evolved over time, then earlier (less restrictive) implementations of the policy are weighted by a “*policy_intensity*” value that is between 0 and 1, and the most recent (more restrictive) version of the policy has a value of 1.

For simplicity, if a given policy has undergone one version change, then the “*policy_intensity*” of the first edition is equal to 0.5, and the value of the second edition is equal to 1. If there have been two version changes, then the “*policy_intensity*” of the first edition is equal to 0.33, the value of the second edition is equal to 0.67, and the value of the last edition is equal to 1, etc.

We compute ‘*policy_intensity*’ using this approach:

1. For non population-weighted policy variables: For a given policy category on a specific date (e.g. “*business_closure*” on March 15, 2020), take the maximum of the mandatory policy intensities for all units lower (e.g. Adm0) than, equal to, and higher (e.g. Adm2) than the analysis unit (e.g. Adm1). Assign this maximum “*policy_intensity*” value to the unit of analysis. If there is no mandatory version of the policy that applies to the unit of analysis, then take the maximum of the optional policy intensities and assign it to the optional policy variable for the analysis unit.
2. For population-weighted policy variables: Take the maximum of the mandatory policy intensities for all units lower (e.g. Adm0) than and equal to the analysis unit (e.g. Adm1), and assign that as the default mandatory intensity for all units higher (e.g. Adm2). If the policy is not mandatory at the analysis or lower unit, then assign the maximum of the optional “*policy_intensity*” value as the default optional intensity for all higher units. For any higher unit that has a specific policy, assign the appropriate version (mandatory or optional) of the policy

variable at that higher unit the maximum of that intensity and the default intensity, with mandatory always taking priority over optional. For all that don't have a specific policy, assign them the default intensity (again, assigning this to the optional or mandatory version as appropriate). Then calculate the population-weighting at the analysis unit level (e.g. Adm1), separately for both optional and mandatory variables. Each higher unit should only have a non-zero intensity for optional or for mandatory (or neither), but not both.

3. For broadly defined policy variables like “*social_distance*” that could encompass a variety of country-specific policies: The “*policy_intensity*” assignment differs by country. If the specific policies employed at the various administrative levels are the same policy, then the approach in (1) is used. If they are different policies within the same broad category, then we add instead of taking the maximum, allow for both optional and mandatory policies, and otherwise follow the approach of (1). This addition is appropriate across different administrative divisions because of (1). If some policies are the same and some are different, we use a combination of addition and taking the maximum over the “*policy_intensity*” values. For instances when we add the “*policy_intensity*” values, once the processed dataset has been constructed and formatted, the last step is to normalize each variable such that it takes values between 0 and 1 (e.g. if the maximum from addition of sub-policies is 1.4, divide that entire column by 1.4). This standardization should again be done separately for each mandatory and optional version of each policy.

China

We obtain data on China’s policy response to the COVID-19 pandemic by culling data on the start dates of travel bans and lockdowns at the city-level from the “2020 Hubei lockdowns” Wikipedia page,⁶³ the Wuhan Coronavirus Timeline project on Github,⁶⁴ and various news reports.

To combat the spread of COVID-19, the Chinese government imposed travel restrictions and quarantine measures, starting with the lockdown of the city of Wuhan, the origin of the pandemic, on January 23, 2020. Immediately following the Wuhan lockdown, neighboring cities followed suit, banning travel into and out of their borders, shutting down businesses, and placing residents under household quarantine. The same policy measures were implemented in cities across China for the next three weeks.

Some lockdowns occurred during the national Chinese New Year holiday (January 24–30, 2020) when schools and most workers were on break. On January 27, 2020, China extended the official holiday to February 2, 2020, while many additional provinces delayed resuming work and opening schools for even longer.⁶⁵ The Chinese New Year holiday is analogous to containment policies such as school closures and restrictions on non-essential work. We do not specifically estimate the effect of this holiday extension, as most cities were in lockdown during the extended holiday, and a lockdown is a

⁶³ [2020 Hubei lockdowns](#)

⁶⁴ [Pratitya/wuhan2020-timeline: 以社会学年鉴模式体例规范地统编自2019年12月起武汉新冠肺炎疫情进展的时间线 \(The timeline of COVID-19 events since December 2019\)](#)

more restrictive containment measure. A lockdown requires all residents to stay home, except for medical reasons or essential work, and only allows one person from each household to go outside once every one to five days (exact policy varied by city).

France

We obtain data on France's policy response to the COVID-19 pandemic from the French government website, press releases from each regional public health site, and Wikipedia.

The French government website contains a timeline of all national policy measures.⁶⁶ Each regional public health agency (*l'Agence Régionale de Santé*) in France posts press releases with information on the policies the région or départements within the région will implement to mitigate the spread and impact of the COVID-19 outbreak.⁶⁷ The Wikipedia page on the 2020 coronavirus pandemic in France has collated information on the major policy measures taken in response to the COVID-19 pandemic.⁶⁸

Starting February 29, 2020, France banned mass gatherings of more than 5,000 people nationwide, while some major sporting events were cancelled and a handful of schools closed to mitigate the spread of the virus. As more COVID-19 cases were confirmed during the following week, additional sporting events were canceled, more schools decided to close, and certain cities and *départements* limited mass gatherings to no more than 50 people, excluding shops, business, restaurants, bars, weddings, and funerals. Some régions closed early childhood establishments (e.g. nurseries, daycare centers) and prohibited visitors to elderly care facilities. On March 8, 2020, France banned mass gatherings of more than 1,000 people nationwide. Other schools, cities, and départements followed suit with additional school closures and limiting mass gatherings. On March 11, 2020, France prohibited all visits to elder care establishments. Starting March 16, 2020, France closed all schools nationwide. Between March 17, 2020 – March 23, 2020, governments at both the national level and région level implemented more restrictive lockdown policies, which included shelter-in-place measures,⁶⁹ the closing of public places,⁷⁰ and banning of outside markets and severely restricting movement outside of the house.⁷¹

We have coded various policies that cancel events and large gatherings as such: any cancellations of professional sporting and other specific pre-scheduled events as the policy variable “*event_cancel*.” The “*no_gathering*” policy variable represents policy measures that banned all events or mass gatherings of a certain size, e.g. no gatherings of over 1,000 people. The “*social_distance*” policy variable includes measures preventing visits to elder care establishments, closures of public pools and tourist attractions, and teleworking plans for workers.

South Korea

We obtained data on South Korea's policy response to the COVID-19 pandemic from various news sources, as well as press releases from the Korean Centers for Disease Control and Prevention (KCDC), the Ministry of Foreign Affairs, and local governments' websites. The policy variables coded in the dataset are: *"welfare_services_closure," "business_closure_opt," "emergency_declaration," "no_demonstration," "religious_closure," "event_cancel," "school_closure," "social_distance_opt," "travel_ban_intl_in_opt," "travel_ban_intl_out_opt," "work_from_home_opt," and "pos_cases_quarantine"*.

On February 28 2020, the KCDC recommended the closure of 14 types of social welfare facilities to reduce the spread of infection among vulnerable groups in the population.⁷² These include childcare centers, vocational rehabilitation centers for the disabled, senior citizen centers, mental rehabilitation facilities, and homeless use facilities. We code this in the variable *"welfare_services_closure"*. Even though it was technically a recommendation, we did not code this policy as optional because a majority of facility types listed in the press release (senior citizen centers, job centers, childcare centers, etc.) are under public administration, so these facilities likely would have followed recommendations. Indeed, some news articles have reported that all children's centers in Busan are closed⁷³ as well as over 3,600 facilities in Seoul.⁷⁴

We created another variable, *"business_closure_opt"*, which applies to two provinces: Seoul and Gyeonggi-do. On March 11, 2020, the mayor of Seoul advised that popular commercial establishments such as karaoke places, clubs, and cyber cafes be closed.⁷⁵ Seven days later, the governor of Gyeonggi-do issued an executive order limiting the usage of commonly frequented commercial establishments and requiring a higher standard of cleanliness.⁷⁶ We coded this as an optional business closure given that the policy discourages usage of these facilities but did not explicitly order them to shut down.

Daegu and Gyeongsangbuk-do have been two of the regions hardest hit by COVID-19. The government of South Korea declared an emergency for those two areas on March 15, 2020.⁷⁷ We incorporated this information into the variable *"emergency_declaration."*

The variable *"no_demonstration"* reflects the efforts of some regions limiting any protests calling for slowing the spread of the outbreak. On February 24, 2020, Incheon stopped a protest in front of the

Incheon Metropolitan City Hall.⁷⁸ Two days later, Seoul prohibited protests in downtown areas where massive demonstrations used to take place.⁷⁹

Many province level COVID-19 policies have targeted religious gatherings at Shincheonji Church of Jesus, since its religious gatherings have been linked to the explosion in the number of cumulative confirmed cases. Provincial governments tried to shut down Shincheonji-related places of worship, and the related policy implementation is encoded in the variable “*religious_closure*.” The regions which utilized this policy option are: Daegu,⁸⁰ Gyeongsangbuk-do,⁸¹ Seoul,⁸² Jeju,⁸³ Gyeonggi-do,⁸⁴ Jeollanam-do,⁸⁵ Gyeongsangnam-do,⁸⁶ Incheon,⁸⁷ Ulsan,⁸⁸ Busan,⁸⁹ Jeollabuk-do,⁹⁰ Chungcheongbuk-do,⁹¹ Gwangju,⁹² Chungcheongnam-do,⁹³ and Daejeon.⁹⁴

Many provinces have also canceled public events organized by local administrative agencies. We code this policy in the variable “*event_cancel*”. The regions which exercised this policy are: Seoul⁹⁵, Daegu⁹⁶, Gangwon-do⁹⁷, Chungcheongbuk-do⁹⁸, Chungcheongnam-do⁹⁹, Sejong¹⁰⁰, Daejeon¹⁰¹,

The policy variable “*school_closure*” has been turned on for the entirety of the Korean time series dataset. This is because all schools were already on vacation during the beginning of the outbreak, and the government then postponed their start dates. At the time of writing, the Ministry of Education announced that schools would be kept closed until April 3, 2020.¹¹² Therefore, this policy variable is always equal to 1 in the dataset.

“*social_distance_opt*” has been turned on from February 29, 2020, when KCDC recommended social distancing as one of the main tools to deal with the outbreak. In their press release, they recommended that “people maintain personal hygiene and practice ‘social distancing’ until the beginning of March, an important point of this outbreak.”¹¹³ In the case of Daegu, the hardest-hit region in the country, we coded the variable as 1 starting from February 22, 2020, based on the statement, “It is recommended for residents in Daegu to minimize gathering events and outdoor activities.”¹¹⁴

The first travel restriction for incoming travelers (“*travel_ban_intl_in_opt*”) was implemented on January 28, 2020. It is worth noting that it was not a total prohibition of incoming visitors; rather, it means inbound travellers were subject to COVID-19 specific emergency measures. KCDC mentioned that starting on January 28, 2020 “any travellers depart[ing] from China [would] be a subject to strengthened screening and quarantine measures.”¹¹⁵ On February 12, 2020, KCDC broadened the list of countries subject to the stricter measures to include Hong Kong and Macau.¹¹⁶ Subsequently, KCDC added Italy and Iran (on March 11, 2020);¹¹⁷ France, Germany, Spain, UK, and Netherlands (on March 15, 2020);¹¹⁸ and any remaining European countries (March 15, 2020)¹¹⁹ to their country list. On March 19, 2020, the policy was expanded to include all travelers arriving at port regardless of country of origin.¹²⁰

This restriction was not limited to inbound travellers. The government also issued advisories on countries where the number of infections had increased, which has been encoded as the variable “*travel_ban_intl_out_opt.*” The first outbound travel alert due to COVID-19 was announced on January 28, 2020: The Ministry of Foreign Affairs (MOFA) issued a Level 2 (Yellow) alert for any travel to mainland China, Hong Kong, and Macau.¹²¹ Later, MOFA added Italy on February 28, 2020,¹²² Japan on March 9, 2020,¹²³ and all European countries on March 16, 2020.¹²⁴ On March 18, 2020, KCDC strongly called for the cancellation or delay of all international travel on non-urgent matters.¹²⁵ It should be noted that the Level 2 alert does not enable the government to prohibit travel to these destinations, which is why the policy was coded as “optional.”

There are four types of travel advisories distributed by the South Korean government: Level 1, Navy; Level 2, Yellow; Level 3, Red; and Level 4, Black.¹²⁶ Travel under the Level 4 alert is prohibited, and the government utilizes legal instruments to enforce the restriction. If people leave the country under the black alert, they will be subject to fines up to ten million KRW, or imprisonment up to a year. However, there is no enforcement instrument for the advisories up to Level 3. In that sense, we stated above that the banning policy does not mean prohibiting travel. Nevertheless, we coded the yellow alert as the first travel ban in our dataset, since Level 2 alerts are issued relatively rarely, such as during a significant demonstration¹²⁷ or military coup.¹²⁸ As a result, we coded the Level 2 alert due to COVID-19 into the dataset for the policy analysis.

The policy variable “*work_from_home_optional*” indicates when KCDC began recommending that people work from home. On March 15, 2020, the KCDC press release stated: “Since contact with confirmed cases in an enclosed space increases the possibility of transmission, it is recommended to work at home or adjust desk locations so as to keep a certain distance among people in the office. More detailed guidelines for local governments and high-risk working environments will be distributed soon.”¹²⁹

On March 22, 2020, the KCDC announced that all inbound travelers from Europe would be tested at the airport and subject to quarantine measures.¹³⁰ Korean citizens and long-term visitors returning from abroad needed to home-quarantine for 14 days (even if they test negative for COVID-19), while short-term visitors would be actively monitored. Inbound travelers with no symptoms were required to stay at temporary facilities while awaiting their test results.¹³¹ We coded this as the policy variable “*pos_cases_quarantine*” modulated by “*policy_intensity*” = 0.25. When this policy was expanded on

March 27, 2020 to include all symptomatic travelers arriving from the US,¹³² we coded this variable with a “*policy_intensity*” = 0.5. On April 1, 2020, these quarantine measures were extended to include inbound travelers arriving from all countries, with exceptions allowed only for limited cases (diplomatic missions etc.).¹³³ This variable was then coded with “*policy_intensity*” = 0.75. Lastly, starting on April 5, 2020, the KCDC announced that inbound travelers who fail to comply with quarantine regulations are subject to imprisonment of up to 1 year or a fine of up to 10 million won for the violation of the Infectious Disease Control and Prevention Act. In addition, persons of foreign nationality who fail to comply may be subject to measures including deportation and entry ban in accordance with the Immigration Act.¹³⁴ We then coded this variable with the “*policy_intensity*” = 1.

Italy

We have obtained data on Italy’s policy responses to the COVID-19 pandemic primarily from the English version of the COVID-19 dossier “Chronology of main steps and legal acts taken by the Italian Government for the containment of the COVID-19 epidemiological emergency”¹³⁵ written by the Department of Civil Protection (*Dipartimento della Protezione Civile*), most recently updated on March 12, 2020. This dossier details the majority of the municipal, regional, provincial, and national policies rolled out between the start of the pandemic to present-day. We have supplemented these policy events with news articles that detail which administrative areas were specifically impacted by the additional policies.

The first major policy rollout was on February 23, 2020, when 11 municipalities across two provinces in Northern Italy were placed on lockdown. These policies included closing schools, cancelling public and private events and gatherings, closing museums and other cultural institutions, closing non-essential commercial activities, and prohibiting the movement of people into or out of the municipalities.

The second major policy rollout was on March 1, 2020, when two provinces and three regions in Northern Italy were placed on partial lockdown. These policies also included closing schools, cancelling public and private events and gatherings, closing museums, closing non-essential commercial activities, as well as limiting the number of people at places of worship, restricting operating hours of bars and restaurants, and encouraging people to work remotely.

The third major policy roll-out was on March 5, 2020, when all schools across the country were closed.

The fourth major policy roll-out was on March 8, 2020 when the region of Lombardy and 13 provinces in Northern Italy were placed on lockdown. These policies included the cancellation of public and

private events and gatherings, closing of museums, encouraging people to work remotely, limiting the number of people at places of worship, restricting opening hours of bars and restaurants, mandating quarantine of people who tested positive for COVID-19, prohibiting the movement of people into or out of the affected area, and restricting movement within the affected area to only work or health-related purposes. Commercial activities were still allowed, as long as they maintained a safety distance of one meter apart per person within the establishment. All civil and religious ceremonies, including weddings and funerals, were suspended. During this same policy roll-out, the rest of the country faced less stringent policies: cancelling public and private events, closing museums, and requiring restaurants and commercial establishments to maintain a safety distance of one meter apart per person within the establishment.

The fifth major policy roll-out was announced on March 9, 2020, and went into effect on March 10, 2020, when lockdown policies applied to Northern Italy were rolled out to the entire country. Lastly, on March 11, 2020, the lockdown was changed to also cover the closing of any non-essential businesses and further restricted people from leaving their home.

After the death toll in Italy surpassed that of China on March 21, 2020, the Italian government increased the severity of their existing policies. Effective March 22, 2020, all non-essential industrial production and factories would be shut down across the country.¹³⁶ Domestic travel was further restricted; people were not permitted to leave the municipality they were currently in except for urgent matters or emergencies.¹³⁷ Lastly, in the hard-hit northern region of Lombardy, the regional government increased lockdown restrictions by banning all individual outdoor exercise or sporting activity.¹³⁸

Policy Intensity: We have modified the policy intensity of three different policy variables: “*home_isolation*,” “*business_closure*,” and “*travel_ban_local*.”

The “*home_isolation*” policy underwent three policy revisions:

1. The least restrictive version of the policy applies to when people were allowed to leave the house for work, health, and essential reasons (“*policy_intensity*” of “*home_isolation*” = 0.33).
2. The moderate version of the policy applies to when people were allowed to leave the house only for health and essential reasons (which includes the ability to go outdoors for individual exercise/sporting activities) (“*policy_intensity*” of “*home_isolation*” = 0.67).
3. The most restrictive version of the policy applies to when people were allowed to leave the house only for health and essential reasons, but were no longer allowed to leave the house for individual exercise/sporting activities (“*policy_intensity*” of “*home_isolation*” = 1).

The “*business_closure*” policy underwent three policy revisions:

1. The least restrictive version of the policy applies to the limiting of restaurant hours (but other commercial activities were permitted) (“*policy_intensity*” of “*business_closure*” = 0.33),

¹³⁶ [Virus News: Italian Industry Shuts Down](#)

¹³⁷ [Italy Coronavirus News: Travel Ban Inside Country](#)

¹³⁸ [Coronavirus: Lombardy region announces stricter measures](#)

2. the moderate version of the policy applies to the closing of all non-essential businesses, (“*policy_intensity*” of “*business_closure*” = 0.67),
3. and the most restrictive version of the policy applies to the closing of all non-essential industrial production and factories, in addition to the closing of non-essential businesses (“*policy_intensity*” of “*business_closure*” = 1).

Lastly, the “*travel_ban_local*” policy underwent two policy revisions:

1. The least restrictive version of the policy applies to when people were not allowed to enter/exit the affected administrative area, (“*policy_intensity*” of “*travel_ban_local*” = 0.5),
2. and the most restrictive version of the policy applies to a more restrictive ban on domestic travel that mandated that people had to stay in the municipality they were currently in (“*policy_intensity*” of “*travel_ban_local*” = 1).

Iran

For Iran’s policy response to the COVID-19 pandemic, we relied on news media reporting as the primary source of policy information (mostly due to translation restrictions). We also relied on two timelines of pandemic events in Iran to help guide the policy search.^{139 140}

The first major outbreak in Iran was connected to a major Shia pilgrimage in the city of Qom that brought Shiite pilgrims from Iran and throughout the Middle East, where they came to kiss the Fatima Masumeh shrine. It is possible that the disease was brought to Qom by a merchant traveling from Wuhan, China.¹⁴¹ In addition, it is believed that the Iranian government knew of the COVID-19 outbreak prior to its February 21, 2020 parliamentary elections, but downplayed the risks associated with the disease as not to suppress voter turnout (given concerns that a low turnout would reflect poorly on its legitimacy).¹⁴² The disease, initially centered in Qom and neighboring Tehran, spread rapidly throughout the country.

As the number of cases grew, the Iranian government started to increase the stringency of its response. The first case was reported on February 19, 2020 (two individuals who both were reported to have died that day). The next day, school closures were announced in the province of Qom and travel in the region was discouraged. By February 22, 2020 the government closed schools in 14 provinces and closed down major gathering sites such as football matches and theaters. By March 5, 2020 schools were closed nationwide and government employees were required to work from home. Home isolation was implemented by the military on March 13, 2020, which the media described as “the near-curfew follows growing exasperation among MPs that calls for Iranian citizens to stay at home had been widely ignored, as people continued to travel before the Nowruz New Year holidays.”

United States

For the United States' policy response to the COVID-19 pandemic, we relied on a number of sources, including the U.S. Center for Disease Control (CDC), the National Governors Association, individual state health departments, as well as various press releases from county and city-level government or media outlets. The CDC has posted and continually updated a Community Mitigation Framework that encompasses both mandatory and recommended policies at a national level.^{144 145} This framework was interpreted by individual states as they each declared their own States of Emergency at various dates, and subsequently released their own community mitigation plans or executive orders. Some of the first states to release such plans include Massachusetts, California, Florida, Washington, and New York.¹⁴⁶ Each respective Community Mitigation Framework included both mandatory and optional policies to prevent the COVID-19 spread. In addition the National Governors Association has served as a resource for individual states' policies in response to COVID-19, updating each states' policy rollout timelines as well as providing links to states' Executive Orders and other official policy documentation.¹⁴⁷ To supplement both national and state level policies and recommendations, data was collected, when possible, for cities and counties that have also taken on the role of providing guidance and implementing policies to mitigate the spread of COVID-19.

There have been a wide range in responses across states since the first case of COVID-19 was announced in Washington State on January 14, 2020. As a result, the CDC began releasing guidance to those at risk of being exposed to the virus. The initial recommendations included travel warnings for specific countries with confirmed cases and sustained COVID-19 spread. Over the course of our dataset, these warnings increased in intensity, changing from warning against inbound and outbound travel to specific countries in both Europe and Asia to warning against travel at all.¹⁴⁸ International travel restrictions were coded as "*travel_ban_int_out*" for outbound travel, and "*travel_ban_int_in*" for inbound travel, with lists of the places to and from which travel was restricted also included. On March 31, 2020, the US changed its global travel warning to Level 4, the highest warning level, which the US Department of State defines as avoiding "all international travel due to the global impact of COVID-19."¹⁴⁹ In addition to the national travel restrictions, individual states also implemented local travel bans, coded as "*travel_ban_local*" as the spread continued to grow, such that anyone entering specific states in which this policy was in effect were required to self-quarantine for 14 days. This ultimately reflected the national policy as well, in that people could still technically travel under a Level 4 warning, but upon arrival to the US, they would be put in a mandatory quarantine for 14 days.

In addition to travel restrictions, as COVID-19 prevalence increased in the world and within the US borders, the CDC began to release additional guidance for healthcare workers, individuals at higher

risk, as well as for state-level action (e.g. travel or social distancing policies).¹⁵⁰ These policies have largely been implemented at the state-level rather than at the national level. Social distancing policies, coded as “*social_distance*” have either recommended or mandated that individuals avoid crowds, stay home as much as possible, delay elective medical procedures, limit or avoid visiting vulnerable populations (such as long-term care facilities or prison facilities), wear masks when outside the home, and stand at least six feet away from others in public spaces. The “*social_distance*” policy category also encompasses the closing of government offices and other public facilities such as libraries or museums.^{151 152} Along the same line of social distance policies, a separate variable was coded as “*no_gathering*” to represent policy measures that banned all events or mass gatherings of a certain size, i.e. no gatherings over a certain number of people (where this number has varied by region).

In addition to social distancing, many governors have mandated statewide school closures at the private and public K-12 and higher education levels, while others have left it up to each school district to decide.¹⁵³ School closures have been coded as “*school_closure*” and once implemented, have been “turned on” for the remainder of our time series, as no schools have reopened since these policies have been implemented.

Business closures, coded as “*business_closure*,” have also been recommended or mandated at the state level. These policies have ranged from shutting down all non-essential businesses, reducing the number of hours a business may be in operation, severely restricting the number of customers that are allowed inside at one time, to prohibiting customers to enter a business, such as in the case of bars and restaurants, where they were only allowed to operate or take-out and delivery services. When business closures have involved shutting down all non-essential operations, “essential” has been defined by each state but is largely similar between states, generally defining essential as food or healthcare providers, as well as basic government operations (i.e. trash collection, mail, water monitoring, etc). To support employees working remotely or staying home when sick, a number of states have also mandated paid sick leave for those who are affected by COVID-19, which has been coded as “*paid_sick_leave*.” There is a separate “*work_from_home*” category that includes measures that require businesses to allow employees to telework, if possible, such that no workers except for those who have essential functions are allowed to work in an office.

At the subnational level, many governors have implemented a statewide mandatory shelter-in-place policy, requiring all individuals to self-isolate within their home or place of residence and limit outdoor activity to essential functions only, which is defined by each state. Shelter-in-place laws have been coded as “*home_isolation*,” and generally are enacted alongside a number of other policies, including business closures, local travel bans, more restrictive gathering sizes, and enforceable social distance rules. Again similar to business closures, the definition of “essential function” has been

¹⁵⁰ [CDC COVID-19 Guidance Documents](#)

¹⁵¹ [NYT Article | "Wondering About Social Distancing?"](#)

¹⁵² [COVID-19 | Get Your Mass Gatherings or Large Community Events Ready for Coronavirus Disease 2019](#)

¹⁵³ [US School Closures due to COVID-19](#)

updated in subsequent policy editions to be more detailed and often stricter, allowing for less activity out of the home.¹⁵⁴

We coded various policies that cancel events and large gatherings as “*event_cancel*”, which is only used when one specific event/gathering is cancelled, for example an election postponement, rather than any event over a certain size, which would instead be coded with the “*no_gathering*” variable. The “*emergency_declaration*” variable encompasses all declarations made indicating a “state of emergency” at the city, county, state, and federal level. This declaration allows the affected area to immediately marshal emergency funds and resources and activate emergency legislation, while also giving the public an indication of the gravity of the situation.

Policy Intensity:

Policy intensity was coded to ensure consistency within the state level for US policy variables as opposed to within the national level as was the case for other countries in our dataset. In the US, policies have largely been enacted and enforced by state governments, with variability between states’ versions of the same policy type as well as the timing of implementation. As a result, we code policy intensity based on the number of editions of the same policy within a state. To demonstrate, we include an example of how we code two different states’ implementing the same policy type below:

- On 3/9/20, 3/16/20, and 3/26/20: Connecticut enacted three editions of the “*no_gathering*” policy, restricting public gathering to no more than 250, 50, and 5 people, respectively.
- On 3/11/20: Florida enacted a “*no_gathering*” policy restricting public gathering to no more than 1,000 people. This is the first and only edition of the “*no_gathering*” policy in Florida.

Thus, Connecticut and Florida’s policy intensities are assigned based only on the number of editions within each of the states rather than comparing the details of the policy between the states (i.e., the number of people allowed to gather). Florida’s “*no_gathering*” policy would therefore be assigned an intensity of 1 since there is only one edition, while Connecticut’s three editions of the “*no_gathering*” policy would be assigned intensities of 0.33, 0.67, and 1, respectively. We feel that assigning policy intensity within a state allows us to better capture the context within which a policy is enacted, for example due to different COVID-19 case loads or variation in population density, which may play a significant role in determining the details and timing of a policy.

Population Data

In order to construct population weighted policy variables and to determine the susceptible fraction of the population for disease projections under the realized and the no-policy counterfactual scenarios, we obtained the most recent estimates of population for each administrative unit included in our analysis. The sources of that population data are documented below.

¹⁵⁴ [NYT Article | "See Which States and Cities Have Told Residents to Stay at Home"](#)

China

City-level population data have been extracted from a compiled dataset of the 2010 Chinese City Statistical Yearbooks. We matched the city level population dataset to the city level COVID-19 epidemiology dataset. As the two datasets use slightly different administrative divisions, we only matched 295 cities that exist in both datasets, and grouped the remaining 39 cities in our compiled epidemiology dataset into "other" for prediction purposes. Cities grouped into "other" because of mismatches have a total population of 114,000,000, or 8.5% of the total population in China.

For these 39 cities that we could not match, we imputed the population by taking the total remaining population (114,000,000) and divided it evenly between these remaining cities. We flag the imputed populations by using the binary variable `"pop_is_imputed."`

France

Département-level populations are obtained from the National Institute of Statistics and Economic database.¹⁵⁵ We used the most up to date estimation of the population in France as of January 2020.

South Korea

We downloaded the number of population by provinces from a webpage administered by the Korean Statistical Information Service (KOSIS).¹⁵⁶ The government agency recently updated the population information of February, 2020, which we used for our analysis.

Italy

Region and province level population data come from the Italian National Institute of Statistics (Istat), estimating total population on January 1, 2019. The datasets for all Italian regions and provinces are scraped from [Istat's website](#) in `get_adm_info.ipynb`.

Iran

Province level population data for Iran comes from the 2016 Census, as listed on the *City Population* website.¹⁵⁷ It is scraped in `get_adm_info.ipynb`.

United States

State- and county-level population data come from the 2017 American Community Surveys dataset, and is downloaded via the *census* Python package¹⁵⁸ in `get_adm_info.ipynb`.

Supplementary Methods

In our Supplementary Methods, we describe several sensitivity analyses performed to assess the robustness of our growth rate impacts and projections of cases averted/delayed.

This section is divided into five analyses:

1. Testing the sensitivity of projected averted/delayed cases to varying epidemiological parameters
2. Testing the sensitivity of our regression model to varying epidemiological parameters
3. Testing the sensitivity of our regression model to changes in lag structure
4. Testing the sensitivity of our regression model to withholding of data
5. Testing the sensitivity of our regression model to changes in policy groupings

1. Sensitivity of projected averted/delayed cases to the removal rate γ and the use of an SEIR framework

We compute the empirical removal rate using aggregated data from the countries for which we observe active cases (i.e., China and South Korea) and estimate a value of $\gamma = 0.079$ (see the Methods section of the main text). This value measures the inverse of the mean duration from being *reported* as infected to being *reported* as recovered (or dead) and may differ from the fundamental epidemiological parameter describing the rate of removal from the pool of infectious individuals. While our estimate implies a recovery period (symptom onset to recovery) that is comparable to some estimates in the literature (median time of 19-23 days, varying based on age group, sex, severity, and mode of detection¹⁵⁹), we test the extent to which our simulation results in Figure 4 depend on this value. One motivation for this exercise is that there may be an unknown delay between the time when a patient becomes non-infectious in reality and the time in which they are recorded in the aggregate data as recovered. Assuming a (likely high) value of 14 days average delay between true recovery and recording this recovery generates an estimate of $\gamma = 0.18$, for example. Differential underreporting of recoveries versus cases, for example, could also bias the estimation of γ .

In addition, the use of an SIR framework may misrepresent the true underlying disease dynamics, and a more general SEIR framework, which includes representation of people exposed to the infection without yet being infectious, may produce more realistic simulations of cases averted/delayed by policy. We also test sensitivity to the use of the SEIR framework, as well as a key parameter in this alternative framework -the assumed rate of transition from exposed to infectious (σ).

We replicate the simulation underlying Figure 4 using an SEIR framework with values of $\gamma = \{0.05, 0.1, 0.15, 0.2, 0.25, 0.3, 0.35, 0.4\}$ and $\sigma \in \{0.2, 0.33, 0.5, \infty\}$, with $\sigma = \infty$ corresponding to the SIR

¹⁵⁹ [Epidemiology and Transmission of COVID-19 in Shenzhen China: Analysis of 391 cases and 1,286 of their close contacts](#)

framework we employ in the main simulation. We present our estimates of the total number of cases under both the no-policy and policy scenarios, as well as the total number of cases averted/delayed by policy. We sum simulated cases across all countries on the last dates of the countries' respective samples. Note that the simulation uses the growth rates derived from our empirical model such that changes in γ and σ correspond to changes in the transmission rate β . β must vary with γ and σ as our data determine the underlying exponential growth rate. We show the results of this sensitivity analysis in Extended Data Figure 7.

Panels (a) and (b) respectively show the simulated number of cases in the no-policy and with-policy scenarios. The number of simulated no-policy cases is decreasing in γ for high σ and increasing in γ for low σ . The number of simulated no-policy cases is increasing in σ for low γ and nonmonotonic in σ for high γ . The number of simulated with-policy cases is increasing in γ and decreasing in σ . Panel (c) shows the number of cases averted due to policy and demonstrates that varying σ or γ can reduce our estimate of cases averted on the order of several million reported cases (up to 10%). Panel (c) shows that higher values of γ produce lower estimates of cases averted for the SIR model ($\sigma = \infty$), but increasing estimates of cases averted for the lower values of σ . Panel (d) plots the content of Panel (c) on the log scale used in Figure 4 of the main text for comparison. For our simulation value of γ , decreasing σ decreases our estimate of cases averted.

Overall, these results show that the basic order of magnitude of the number of cases averted is preserved within this reasonable range of potential γ values in the SIR framework and σ values in the SEIR framework.

2. Sensitivity of exponential regression model to varying epidemiological parameters

The model we use to estimate the impacts of policy on growth rates assumes exponential growth, which is typically valid for early-stage disease outbreaks. If growth is not exponential, there exists the potential for bias in estimated coefficients. There are three primary reasons why an early-stage outbreak could exhibit non-exponential growth in the absence of policy intervention:

1. The infection spread may progress quickly, lowering the susceptible fraction of the population to a degree that materially affects the infection spread, transitioning the outbreak away from the exponential “early stage” regime.
2. In a disease with a substantial latent period, the growth of infections is only asymptotically exponential.¹⁶⁰ At any given moment in time, the instantaneous growth rate may differ from a steady-state exponential growth rate.
3. When analyzing growth in cumulative infections, as we do for countries where active infection data are unavailable, growth is similarly only asymptotically exponential.

¹⁶⁰ [Estimating epidemic exponential growth rate and basic reproduction number](#)

In our dataset, 95% of administrative units have susceptible fractions above 0.93 on their last analysis day and all have susceptible fractions above 0.78, indicating that the first reason is unlikely to induce substantial bias in our results. When the transmission rate of a disease declines due to anti-contagion policy, the growth rate in infections decreases with a lag due to the dynamics associated with the latent period. Because of this, exponential models estimating the average treatment effect (ATE) of a policy may underestimate the true reduction seen from a policy because they include days in which the growth rate was still higher than the new steady state growth rate. Finally, in the early stages of an outbreak, the number of active cases will dominate the number of recovered/deceased patients and thus the differences in growth of active and cumulative cases is likely to be small.

To test the robustness of our regression approach, we construct simulated outbreaks in which we control demographic, policy, and epidemiological parameters. We then use a variant of the regression model (Eq. 7) from the main text to estimate the no-policy growth rates and the effects of each policy. In this simulation, we do not include any fixed effects to control for day-of-week (δ) and changing testing regime (μ) effects. These variables are not simulated as these are primarily measurement controls and their effects would be directly absorbed by the corresponding regression parameters if simulated. We compare the coefficient estimates to the “true” values used in the simulation.

To capture the impact of disease latency, we use an SEIR model framework to generate synthetic outbreaks. We simulate 12,000 45-day outbreaks at hourly timesteps, starting with a no-policy exponential growth rate of 0.4 (similar to those estimated in our main analysis) and a single exposed individual. We adjust this asymptotic exponential growth rate to account for three synthetic policies that turn on at random times, each with a known effect (-0.05, -0.1, and -0.2). For each subset of 1,000 simulations, we use one of four plausible values for the mean latency period, σ^{-1} (0, 2, 3, and 5 days), and one of three plausible values for the mean infectious period, γ^{-1} (3, 5, and 20 days). We choose a wide range of these variables due to substantial uncertainty over the epidemiological characteristics of the novel coronavirus,¹⁶¹ and a nonexistent latency period is included for comparison to an SIR-like data generating process. The mean transmission rate per infected person per day, β , is derived from the asymptotic growth rate, the mean latency period, and the mean infection period by solving for the eigenvalues of a SEIR system,¹⁶² which yields:

$$\beta = \frac{(g+\gamma)(g+\sigma)}{\sigma}.$$

We apply exponential noise to β for each simulation and at each timestep, and contribute additional gaussian noise to σ and γ (standard deviations of 0.01 and 0.03, respectively). We add additional gaussian “measurement noise” to the instantaneous growth rates after simulation but before running our regression (standard deviation of 0.1). Cumulatively, this results in an average root-mean-squared-error (RMSE) in regressions across all 12,000 simulations of ~0.11, which matches the RMSE of daily growth rate values across all six countries in our main analysis.

The dynamic model outputs a time series of susceptible (S), exposed (E), infectious (I), and removed (R) individuals, as a fraction of the total population. We use both I and I+R as the left-hand-side

¹⁶¹ [MIDAS Network Online COVID-19 Portal: Parameter Estimates](#)

¹⁶² [Estimating epidemic exponential growth rate and basic reproduction number](#)

variables in our regression framework. The former corresponds to the analysis we run for countries in which we observe active cases and the latter to countries in which we observe only cumulative cases. We assume the majority of the “exposed but not infectious” population will not yet have been tested and will not appear in any of the datasets used in the main analysis. Our right-hand-side variables consist of the binary policy variables, allowing only for contemporaneous effects. This matches our main specification for all countries except China (where data availability allows for the estimate of lagged effects) and provides the most challenging environment in which to estimate the effect of policy in a dynamic system.

Results are presented in Extended Data Figures 8 and 9. While it is possible to simulate outbreaks consisting of innumerable parameter combinations and noise distributions, we display those that seem most relevant for evaluating the robustness of our main analysis. Our associated GitHub repository contains a Jupyter notebook for readers to further examine the effect of simulation configurations on regression model robustness.

Figures 8 and 9 are each split into two panels (a) and (b). Panel (a) of each figure shows simulations in near-ideal data conditions, in which we observe active infections within a large population. This means that the susceptible fraction of the population remains high during the entire sample period. For example, these conditions are similar to those in our real data for Chongqing, China. Panel (b) of each figure shows simulations in a non-ideal data scenario where we are only able to observe cumulative infections in a small population. In these simulations, the susceptible fraction declines to values as low as 33% of the population. For example, these conditions are similar to those in our real sample of data for Cremona, Italy.

Figure 8 demonstrates that our model recovers unbiased estimates of the no-policy growth rate under all conditions simulated. Because the growth rate prior to policy has likely approached its asymptotic rate by the time we begin our regressions, variance in our no-policy growth rate estimates comes from noise in the disease parameters and measurement. The ability to recover unbiased estimates of this value has important implications for our estimate of the total number of cases averted/delayed to date, as this number is primarily driven by the counterfactual number of cases we would expect to see in a world in which no anti-contagion policy was enacted.

Figure 9 demonstrates that our model recovers unbiased estimates of the cumulative effect for a disease with very short latency. As the latency period increases, the model begins to slightly underestimate the true effect of policy (i.e. it predicts a less negative value), due to the decay time over which a shock to transmission rate propagates to a new steady-state growth rate. The underestimate is reduced in situations where we are able to directly observe active infections and is increased when we can only observe cumulative infections. Note that statistical uncertainty in these estimated parameters dominates potential biases, even in “worst case” data conditions.

We conclude that biases (due to the use of an exponential model) in our estimates of the no-policy growth rate are essentially zero and are likely to be small and negative for our estimates of policy

effectiveness. If present in the data, such biases would cause us to modestly understate the effectiveness of anti-contagion policies.

3. Sensitivity of estimates to changes in lag structure

Existing evidence has not demonstrated whether policies should affect infection growth rates in the days immediately following deployment. It is therefore not clear *ex ante* whether the policy variables in Eq. 7 should be encoded as “on” immediately following a policy deployment. As a robustness check, we estimate “fixed-lag” models in which a fixed delay between a policy’s deployment and its effect is assumed. Specifically, we assume that policies cannot influence infection growth rates for L days, recoding a policy variable at time t as zero if a policy was implemented fewer than L days before t . We re-estimate Equation (7) for each value of L and present results in Extended Data Figure 5 and Supplementary Table 5. If a delay model is more consistent with real world infection dynamics, these fixed lag models should recover larger estimates for the impact of policies and exhibit better model fit.

Panel b of Extended Data Figure 5 displays the R^2 associated with each country-level fixed lag model with fixed lag lengths ranging from no fixed lags up to a 15 day fixed lag. In-sample fit generally declines or remains unchanged if policies are assumed to have a delay longer than 4 days. Panel c of Extended Data Figure 5 plots the estimated effects for no lag (the model reported in the main text) and for fixed-lags between one and five days. Estimates generally are unchanged or shrink towards zero (e.g. *Home isolation* in Iran), consistent with mis-coding of post-policy days as no-policy days.

In Supplementary Table 5, we show our estimates of the effect of all policy interventions in each country (analogous to the average difference between red and blue markers in Figure 3 of the main text) using a fixed lag of up to 5 days. The estimated effects are broadly consistent across different lag lengths; however, the magnitude of the effect size declines slightly with increasing lag lengths. If policies take several days to impact infection growth rates, we would expect effect sizes to increase rather than decrease with lag lengths. Our finding of declining effect sizes is more consistent with contamination of the “control” group, where policies are incorrectly encoded as zeros after they have been deployed.

4. Sensitivity of estimates to withholding of data

To ensure that the estimates from our regression model are robust to the withholding of data, we re-estimate our main model k_c number of times for each country, where k_c is the number of first level administrative units (“Adm1,” i.e. state or province) in country c . In each of the k_c regressions for country c , we withhold data from one Adm1 unit when we estimate the effects of policy interventions on growth rates. The results of this exercise are displayed in Extended Data Figures 3 and 4.

5. Sensitivity of estimated growth rates to changes in policy groupings

In our main regression model, due to the limited length of our time series data and instances where multiple policies are deployed on the same date, we group certain policy interventions together. We group policies together that have similar objectives (e.g. “*travel_ban_local*” and “*transit_suspension*” would be one group, “*event_cancel*” and “*no_gathering*” would be another) and keep certain policies separate (i.e. “*business_closure*,” “*school_closure*,” “*home_isolation*”) where possible.

To test the sensitivity of our results to the grouping of policy interventions, we also estimate a model where the policies are estimated without grouping. Extended Data Figure 6 panel a shows the estimated infection growth rates and no-policy counterfactual growth rates using the model with disaggregated policies. Additionally, in Supplementary Table 4, we compare the effect of policy interventions in each country when the effect of all policies are estimated separately (“Disaggregated Model”) and when they are grouped into policy packages as in our preferred specification (“Main Specification”). We find the estimated impact of policy interventions on case growth rates is robust to this alternative specification.

Supplementary Tables

Supplementary Table 1 | Number of unique anti-contagion policies in this study tabulated by administrative divisions of each country.

Country	Adm0	Adm1	Adm2	Adm3	Total
China	0	4	133	0	137
France	8	1	50	0	59
Iran	5	17	0	0	22
Italy	14	29	95	77	215
South Korea	20	39	0	0	59
United States	36	682	418	31	1167
Total	83	772	696	108	1659

This table reports the policy data that have been collected at various levels of administrative divisions in each country. “Adm0” represents the country level, and higher “Adm*” numbers indicate smaller administrative subdivisions, which are specific to each country. Each policy is counted at the highest resolution administrative unit in which the policy is applied differentially. For example, if a country has ten regions at the “Adm1” level, and a policy is applied across five of those regions, the policy is counted as five separate “Adm1” policies rather than a single “Adm0” policy. National policies are counted only once as “Adm0.”

Supplementary Table 2 | Estimates of no-policy infection growth rates and case doubling time using different samples from Wuhan, China.

This table reports the raw epidemiological data in Wuhan, China and our estimates of infection growth rates and case doubling times prior to the city-wide lockdown on January 22, 2020, utilizing different sample periods to estimate these values. Column (1) provides the dates of observations. Columns (2) and (3) show raw official epidemiological data: the number of cumulative cases and the number of active cases (= *cumulative cases* - *recoveries* - *deaths*), respectively.

¹⁶³Wu, J.T., Leung, K., Bushman, M. et al. Estimating clinical severity of COVID-19 from the transmission dynamics in Wuhan, China. *Nature Medicine* 26, 506–510 (2020). <https://doi.org/10.1038/s41591-020-0822-7>

¹⁶⁴Li, Qun, Xuhua Guan, Peng Wu, Xiaoye Wang, Lei Zhou, Yeqing Tong, Ruiqi Ren et al. "Early transmission dynamics in Wuhan, China, of novel coronavirus-infected pneumonia." *New England Journal of Medicine* (2020).

We show data from Wu et al. (2020),¹⁶⁵ which match our data in the overlapping periods; in the interest of space, we do not display raw data used in Li et al. (2020), but they are similar with small differences. Columns (4) and (5), report estimates of pre-policy infection growth rates and case doubling times (in days) using different start dates, respectively. Specifically, we set the sample start date as the date in column (1) and the end date of the sample (used for estimating our no-policy growth rate) fixed at January 22, 2020 (the day prior to city-wide lockdown), using the time series data between these two dates to estimate the parameters in columns (4) and (5). Column (6) provides notes on these data. Using a start date of 12/10/19, the same as Wu et al (2020), we obtain an estimated case doubling time of 5.7 days, similar to their estimated 5.2 days (they use an alternative structural modeling approach). As described in our Supplementary Notes on Epidemiological Data in China, we only use data in China beginning 1/16/20 because the first national guidelines for diagnosis were issued on 1/15/20. Prior to that date, there did not exist a consistent case definition to identify the earliest 41 confirmed cases in Wuhan.¹⁶⁶ Additionally, the documented lack of testing capacity in the province of Hubei before 1/16/20 raises concern about data quality during that time period.¹⁶⁷ These concerns about data quality appear consistent with irregularities in the official record of cumulative cases (column 2). For example, official cumulative cases decreased on 1/9/20, which should not be possible. Additionally, no new cases were reported between 1/9/20 and 1/15/20, when at least roughly five new cases per day should have been reported if case doubling time actually was 5.2 days. The reliability of these official reports during the 1/9/20-1/15/20 period has been called into question, with news sources suggesting that people who were likely to have been infected by COVID-19 in that period of time (and deaths attributed to the disease) were not counted in the official tally.^{168,169} These data quality concerns motivate our use of the 1/16/20 start data for our sample in China, which provide an infection growth rate of 0.36 and case doubling time of 1.95 days (gray) using only the time series in Wuhan. These estimates are broadly consistent with our estimates from all other countries we examine, except Iran, and the global average growth rate of 0.37 we estimate (see Figure 2A in the main text).

Testing regime change on Mar. 05, 2020	0.003	0.004			
Observations	3,698				
R-squared	0.52				

*** p<0.01, ** p<0.05, * p<0.1

This regression includes city fixed effects and clustered standard errors at the day level.

b. South Korea

Dependent variable: Growth rate of active cases (Δ log cases per day)

Variables	Coefficient	Std. Error	Coefficient	Std. Error
<i>Policy variables:</i>			-0.494***	0.150
Social distance (optional)	-0.083**	0.038		
Social distance (mandatory)	-0.304**	0.151		
Emergency declaration	-0.127***	0.047		
Quarantine positive cases	0.0202	0.019		
<i>Testing regime dummy variables:</i>				
Testing regime change on Feb 20, 2020	0.0742	0.087		
Testing regime change on Feb 29, 2020	0.040**	0.019		
Testing regime change on Mar 22, 2020	-0.010	0.023		
Testing regime change on Mar 27, 2020	-0.039	0.038		
Observations	595			
R-squared	0.28			

*** p<0.01, ** p<0.05, * p<0.1

This regression includes province fixed effects, day-of-week fixed effects, and clustered standard errors at the day level.

"Social distance (optional)" includes recommended policies related to social distancing, e.g. no gathering, work from home, and closing businesses such as karaoke and cyber cafes.

"Social distance (mandatory)" includes prohibiting rallies, closing churches, and closing welfare service facilities.

c. ItalyDependent variable: Growth rate of cumulative confirmed cases ($\Delta \log$ cases per day)

Variables	Coefficient	Std. Error
<i>Policy variables:</i>		
Other social distance	0.148**	0.067
School closure	-0.106	0.070
Travel ban	-0.303**	0.147
Quarantine positive cases	-0.076	0.051
Business closure	-0.142	0.107
Home isolation	0.069	0.060
Observations	2,898	
R-squared	0.29	

*** p<0.01, ** p<0.05, * p<0.1

This regression includes province fixed effects, day-of-week fixed effects, and clustered standard errors at the day level.

"Other social distance" includes policies for working from home, maintaining 1 meter distance from others in public, and prohibiting public and private events.

Effect of all policies combined

Coefficient	Std. Error
-0.409***	0.119

d. IranDependent variable: Growth rate of cumulative confirmed cases ($\Delta \log$ cases per day)

Variables	Coefficient	Std. Error
<i>Policy variables:</i>		
Travel ban (opt), work from home, school closure	-0.285***	0.079
Home isolation	-0.151***	0.033
<i>Testing regime dummy variable:</i>		
Testing regime change on Mar 13, 2020	-0.075	0.096
Observations	548	
R-squared	0.30	

*** p<0.01, ** p<0.05, * p<0.1

This regression includes province fixed effects, day-of-week fixed effects, and clustered standard errors at the day level.

"Travel ban (opt), work from home, school closure" policies were enacted March 1-5, 2020 which overlaps with missing provincial case data in Iran on March 2-3, 2020.

Effect of all policies combined

Coefficient	Std. Error
-0.436***	0.068

e. FranceDependent variable: Growth rate of cumulative confirmed cases ($\Delta \log$ cases per day)

Variables	Coefficient	Std. Error
<i>Policy variables:</i>		
Other social distance	-0.227***	0.070
School closure	-0.005	0.039
National lockdown	-0.048*	0.025

Observations	1,235			
R-squared	0.28			

*** p<0.01, ** p<0.05, * p<0.1

This regression includes state fixed effects, day-of-week fixed effects, and clustered standard errors at the day level.

"Other social distance" includes policies such as closing libraries, maintaining 6 feet distance from others in public, and limiting visits to long term care facilities.

These regression tables **a-f** display the results from our main model estimating the effect of policy on daily COVID-19 infection growth rates in China, South Korea, Italy, Iran, France, and the United States. The regression model is estimated separately for each country, allowing for the policy type to have different average treatment effects for each country.

Supplementary Table 4 | Estimated Effect of Actual Policies on Infection Growth Rates With and Without Grouping Policies

Country	Main Specification (policies grouped)		Disaggregated Model (policies separate)	
	Effect size	95% CI	Effect size	95% CI
China	-0.156	(-.187, -.126)	-0.156	(-.187, -.126)
France	-0.139	(-.214, -.064)	-0.195	(-.373, -.018)
Iran	-0.362	(-.497, -.227)	-0.305	(-.455, -.156)
Italy	-0.241	(-.373, -.108)	-0.243	(-.379, -.106)
South Korea	-0.248	(-.423, -.073)	-0.210	(-.377, -.044)
United States	-0.092	(-.158, -.027)	-0.092	(-.165, -.018)

Average effect of all policies on infection growth rates in our sample (analogous to the average difference between red and blue markers in Figure 3 of the main text) using our main specification, where the impact of grouped policy interventions are estimated jointly, compared to a disaggregated model where the effect of all policies are estimated simultaneously but without grouping them (See Supplementary Methods 5). In our main specification, policies are grouped due to limited data. We group policies that have similar objectives (e.g. “*travel_ban_local*” and “*transit_suspension*”) or are deployed very close in time. We keep other policies separate where possible (e.g. “*school_closure*” and “*home_isolation*”). In the disaggregated model, no policies are grouped and individual policies estimates are noisier, however combined effects are similar.

Supplementary Table 5 | Estimated Effect of Actual Policies Combined on Infection Growth Rates Using Alternative Models that Assume Lagged Effects Of Policies

Country	Statistic	0 Day Lag	1 Day Lag	2 Day Lag	3 Day Lag	4 Day Lag	5 Day Lag

	R^2	0.28	0.28	0.28	0.29	0.29	0.29

Average effect of all policies on infection growth rates in our sample (analogous to the average difference between red and blue markers in Figure 3 of the main text) using models with different assumed delays of policy impact, ranging from a one day lag to a five day lag. The “0 Day Lag” column corresponds to the estimates reported in the main text. For models with non-zero lag, the lag structure of the estimating equation is such that for a model with an L day lag, the policy intervention implemented on day t is assumed to have no impact on infection growth rates until day $t+L$. As in the main text, for China and Korea, the reported effect size is the policy impact on the growth rate of active cases, where in the other countries cumulative cases are used. See Supplementary Methods 3 for a discussion of these results.
